

Considerations of the original technique

First of all, our team used the technique of interview. The interview was structured and applied in the same way with some improvisation. We collect data direct from the users about how their system or protocol works and we have the opportunity to visualize some papers, protocols, reports, and information from their work's environment that give us more feeling about them with their actual system.

How the team did implement the technique

We prepared a basic guide of questions but in the heat of the conversation we improvised some questions to collect more data and to have the most possible information about their environment. To keep information at hand, we used manual notes and audio recordings, obviously with verbal consent.

Outcome of the technique

The findings of the techniques are the need to view general information quickly without opening the entire file, frustration with repeating data in each session, desire to access from different devices and insights grouped in functional categories like access, navigation, type of users, and clinical documentation.

How could improve the technique to collect data

The firsts problems founded were that some responses were vague because users were unfamiliar with thinking about software and misunderstanding. Then the interview time were longer than expected. For some possible improvements we have been thinking about use some visual support techniques during the interview like early wireframes, use case diagrams, prototypes or flow maps. And to finalize, to make shorter interviews.
