Key points of the Lean UX technique

First, there is a dilemma about traditional UX techniques and Lean UX technique. Lean UX it's based on hypotheses and assumptions, while Traditional UX it's based on detailed documentation and detailed requirements, meaning that lean UX techniques focus on experimentation. Other key points are the cycle of life of the technique, which is iterative and in short cycles, and the need to collaborate with the entire team, focused on obtaining feedback and doing more hypotheses, experimenting and creating prototypes to be in the same constant cycle and improve.

Lean UX Technique on the Team's process

In our project, we could considerate a lean technique the methodology of our team. Focusing about the attribute of usability, our team was doing assumptions in how to implement the usability in our project, starting with assuring usability will be in our UX design leading to a more detailed and specific understanding of what it's usability and how to measure it. Under the pressure of giving deliverables, we worked in short cycles with constant feedback, leading to an improvement in the description of the project. The bad part of this it's nothing was planned but we worked under the key principles of lean UX.

How much effort would require the Team's process to be considered lean?

Based that Traditional UX techniques focus on develop something defined and unilateral, the team of UX have one job, neither big or small, there's one job to do, with assuring the quality of the task. While, the lean technique focused on a cycle of derivable to have a feedback and going back to the cycle. This means the teams of lean UX will have to improve the same task till acceptance. If the time it's enough, and the resources are the necessary, the benefits could be satisfactory but with more work to do.
