

Usability vs UX

HCI, Usability and UX

HCI it's the subject that studies all the environment of how the human interact with computers, designing efficient and easy ways to use including a lot of subject, branches and concepts of the study in psychology, informatics and design. Usability it's the concept within HCI that means how easy it's a system to be learned and used. UX it's a concept that includes usability but the same as emotional, aesthetics and satisfaction factors.

Difference between Usability and UX.

Usability focuses on efficiency and easy to use and can be measured with metrics like time to finish a certain task, error rate, ease of use, etc. UX study how the user feels with the system and can be measured with emotions and design perception. In one hand, your system can have usability and be easy to use and learn but with no engage factor. In the other hand, you can have a good UX that can be attractive but can frustrate the users and cause them to abandon the system. In our project, a good example can be the system that can register and consult files quickly without mistakes providing a good usability factor but with bad UX the interface it's monotonous, unattractive and with no sense of confidence and professionalism.

UX specific feature

We are examining the possibility of including a progress bar or a dynamic checklist that show to the user how many sections of the expedients have been completed. The UX attribute involved could be the conscience of the state of the system or the satisfaction that the system can provide because of the order and control. The UX metric can be measured with the reduction of forgetting critical sections or the reduction of time to complete expedients and we can ask if the users felt more control about the process.
