

When we use **Personas** in design, we create imaginary characters that represent the people who will use the system. Each **Persona** has a name, a job, goals, and problems. This helps us understand the users better. In this part, the important thing is not only to create those **Personas**, but to use what we learned from them to design the screens or prototype. That way, we don't design by guessing, we design thinking about real people and what they truly need.

In our psychology clinic project, we used a Persona named Alejandra. She is a therapist in training, studying for her master's degree, and already has some experience. Alejandra wants to register and view patient information easily. So, in the prototype, we added a section where she can quickly see the clinical history and write notes for each session. We also used another Persona called Luis, the clinic coordinator. He needs to check if therapists are filling out patient records correctly. To help him, we added reports that show if the files are complete or not, and some statistics to check everyone's progress.

These two Personas show us how can Personas help us to make a better design. For Alejandra, we made the system easy to use, so she doesn't waste time and can focus on her patients. The notes are organized and everything is easy to find. For Luis, we thought about how to give him a clear summary of what's happening in the clinic. This helps him support his team and keep everything under control. Thanks to this, the system is more useful, easier to use, and made for the real people working there.
