

Alprompt

In this activity, I focus in the attribute **learnability**, because our system is for therapists in training that maybe don't have experience using digital tools. So we want them to understand fast how to use the basic things, without someone explaining every step.

I used **ChatGPT** to help me. I write a prompt in spanish saying that I need 4-6 tasks to test learnability in a system of clinical records. I explain that is for psychologists in training and the system is for manage patient information. The IA give me a good list of tasks, very fast. Like in 2 minutes I got everything. Some tasks was similar to what we already have, but one or two were new and interesting.

I think that using AI is faster, and good for start or get ideas when you feel blocked. But manual way is better when you already know your users and want more real tasks.

We can use AI:

- When we have not much time
- When we want inspiration or more options
- When we don't know how to start

We better do it manually:

- When the project is very specific
- When we already know what the users need
- When the context is emotional or sensitive

IA Tool Used: ChatGPT

Prompt:

Diseña una prueba de usabilidad para un sistema de gestión de expedientes clínicos usados por terapeutas en formación, quiero evaluar el atributo de usabilidad "facilidad de aprendizaje" (learnability). Sugiere de 4 a 6 tareas que ayuden a medir si los usuarios pueden aprender a usar el sistema de forma rápida y sin mucha ayuda; las tareas deben ser realistas y representar acciones comunes dentro del sistema. Gracias.
