

It's easy for people to confuse User Interface (UI) and User Experience (UX), but they are not the same. UI is about how a page or app looks. The colors, buttons, texts, and how everything is organized. On the other hand, UX is about how it feels to use that page or app. If it's easy to understand, fast, and if the user can do what they need without problems. The article from WPMU DEV explains that something can look beautiful, but if it's hard to use then it's not very useful.

In the psychology clinic project, there are two clear examples of this. A UI example is the design of the form to register a new patient. It needs to look clear, with easy-to-read text and understandable buttons. A UX example is when a therapist uses the system to find a patient's file. If they can find it quickly and with few steps, then the experience is good.

In the first example, if the form looks clean and organized, the secretary can fill it out without errors or confusion. In the second example, if the system is well-designed, the therapist can find the needed information without wasting time. These two cases show how UI and UX are different, but both are important for the system to work well and be comfortable for users.
