

UIvsUX

The article of Balkhi (2025) explains that the UI (User Interface) refers to the visual elements like the buttons, screens, menus and every component the user interacts with. On the other side the UX (User Experience) is everything that covers the user's interaction with the product in its totality, including its emotions and perceptions during the use of the system.

Based on my own work:

Example of UI

The pages where the therapist can check his patients

Example of UX

The therapist can add a new patient at any time by just clicking at the button, the process is intuitive, quick and without friction.

In my opinion, the UI is an essential part of the UX because it's the base for the structure and the action calls of the user, depending on the color and the design in the UI, the UX can change.
