

TraceabilityAtt

In our project, we choose **efficiency** as the main usability attribute, because the therapists using the system need to find a patient record fast, especially before a session. We tried to include this in the prototype by reducing steps, like making filters easy to find, and letting users go back fast to the main screen. Important actions are always visible and don't require many clicks.

To measure this, we focused in **task time and number of steps**. We didn't use a complex method, just a stopwatch and some notes. We also looked if they hesitated or got stuck. We talked about using SUS, but we think it's not specific for this, so we skip it and go for direct observation.

The data we collected was:

- Time in seconds to complete each task.
- Number of clicks or screens visited.
- If they asked help or didn't know what to do.

We decided these because they are easy to measure and show if the user can really work fast or not. Also, most of our users are students or therapists, not tech experts.

Alternative data we could use includes: **number of misclicks**, how many times they click "back", or even screen recordings to analyze their path. That would give us more info about what confuses them.
